ASSIGNMENT I

Upload one file (text/ html/ R) with the R code and detailed comments and conclusions addressing the following questions.

The code, the comments, and the final conclusions presented will be graded.

Deadline: Wednesday 20/11/2024, 23.00

The salary data frame contains information about 474 employees hired by a Midwestern bank between 1969 and 1971. It was created for an Equal Employment Opportunity (EEO) court case involving wage discrimination. The file contains beginning salary (SALBEG), salary now (SALNOW), age of respondent (AGE), seniority (TIME), gender (SEX, coded 1 = female, and 0 = male) among other variables.

- 1. Read the dataset "salary.sav" and use the function str() to understand its structure.
- 2. Get that summary statistics of the numerical variables in the dataset and visualize their distribution (e.g. use histograms etc). Which variables appear to be normally distributed? Why?
- 3. Use the appropriate test to examine whether the beginning salary of a typical employee can be considered to be equal to 1000 dollars. How do you interpret the results? What is the justification for using this particular test instead of some other? Explain.
- 4. Consider the natural logarithm of the difference between the beginning salary (**salbeg**) and the current salary (**salnow**). Construct a new variable log(salnow–salbeg) and test if, on average, it is equal to one. Make sure that the choice of the test is well justified.
- 5. Is there any difference on the beginning salary (**salbeg**) between the two genders? Give a brief justification of the test used to assess this hypothesis and interpret the results.
- 6. Cut the AGE variable into three categories so that the observations are evenly distributed across categories (Hint: you may find the cut2 function in Hmisc package to be very useful). Assign the cut version of AGE into a new variable called age_cut. Create the following variable with the name **relSal**:

Relative salary rise =
$$\frac{Current \ salary - Beginning \ salary}{Current \ salary} \times \frac{1}{time}$$

Investigate if, on average, the relative salary rise (**relSal**) is the same for all age groups. If there are significant differences, identify the groups that differ by making pairwise comparisons. Interpret your findings and justify the choice of the test that you used by paying particular attention on the assumptions.

- 7. Investigate if, on average, the relative salary rise (**relSal**) is the same for all job categories. If there are significant differences, identify the groups that differ by making pairwise comparisons. Interpret your findings and justify the choice of the test that you used by paying particular attention on the assumptions.
- 8. By making use of the factor variable minority, investigate if there are differences in the proportions among the job categories.
